

## 4. TURING MACHINE

## \* Introduction to Turing Machine

→ "Turing m/c is mathematical model which consist of:  
 • an infinite length tape divided into cells on which  
 • input is given. It consisting head which reads the i/p tape.

A state register stores the state during a function call. After reading

an IUPAC symbol, it is replaced with another symbol.

~~(iii) If its internal state is changed; and it moves from one~~

cells to the right or left at 15° in the plane of the cell sheet.

- If TM machine reaches to final state, the i/p string is accepted otherwise rejected.

### Example 2: Turing Machine

- Turing machine is more powerful than PDA.

→ tuning switch via capable less performing computation

on IIP status producing a review result: `unknown`

## \* Applications of Turing Machine:

- 1) To read or write infinite tape.
- 2) to solve problem in computer science & testing limit of computation.
- 3) it is used to simulate other turing machine.
- 4) Turing m/c is used to reverse string of any character.
- 5) it is used in algorithmic information theory
- 6) Turing m/c is used for high performance computing & machine learning, AI engg and computer network.
- 7) Turing m/c is used to perform computation for computer system.
- 8) ~~Turing m/c is used in theory of computation~~

## \* Different ways of extending TM is equivalent to Turing

→ In std TM, the tape is semi-infinite. It is bounded on the left and unbounded on the right side.

Some of the Extension of TM is given below:

- 1) Tape is of infinite length in both the direction.
- 2) Multiple heads and single tape.
- 3) Multiple tape with each tape having its own independent head.
- 4) K-dimensional tape.
- 5) Non-deterministic turing m/c.

### 1) Two-way infinite turing m/c:

In 2-way infinite TM, there is an infinite sequence of blank on each side of i/p string. In instantaneous description, these blocks are never shown.

### 2) A turing m/c with multiple head

→ All TM with single tape can have multiple heads.

Let's consider TM with two heads H<sub>1</sub> & H<sub>2</sub> such that each head is capable of performing read/write operation.

B a a b a a B B

↑<sub>H<sub>1</sub></sub> ↑<sub>H<sub>2</sub></sub> ← TM with two head

### 3] Multi-tape Turing Machine

→ Multi-tape turing mtc has multiple tape tuples with each tape having its own independent head.

(a) Let's consider case of two tape turing machine shown in fig.

Tape-1     $B \overset{a}{\underset{\text{head}}{|}} b \overset{a}{\underset{\text{head}}{|}} a \overset{b}{\underset{\text{head}}{|}} b \overset{b}{\underset{\text{head}}{|}} a \overset{B}{\underset{\text{head}}{|}} B \overset{B}{\underset{\text{head}}{|}}$

Tape-2     $B \overset{a}{\underset{\text{head}}{|}} a \overset{b}{\underset{\text{head}}{|}} b \overset{b}{\underset{\text{head}}{|}} a \overset{b}{\underset{\text{head}}{|}} b \overset{a}{\underset{\text{head}}{|}} a \overset{B}{\underset{\text{head}}{|}} B \overset{B}{\underset{\text{head}}{|}}$

#### Two-Tape Turing Machine

- The transition behaviour of a two-tape turing mtc can be defined as given below for various changes:

$$\delta(q_1, a_1, a_2) = (q_2, (S_1, M_1), (S_2, M_2))$$

where,

$q_1$  is current state.

$q_2$  is next state.

$a_1$  symbol head on tape 1

$a_2$  symbol under head on tape 2.

$S_1$  is symbol written in current cell on tape 1.

$S_2$  is symbol written in current cell on tape 2.

$M_1$  is the movement (L,R,N) of head on tape 1.

$M_2$  is the movement (L,R,N) of head on tape 2.

#### \* Limitations of Turing Machine

→ 1) Computational Complexity theory limitation is that they do not model strength of particular arrangement.

2) Concurrency limitation is that they do not model concurrency well.

limitation is that they do not model concurrency well.

3) They will always halting in concurrent system with no i/p.

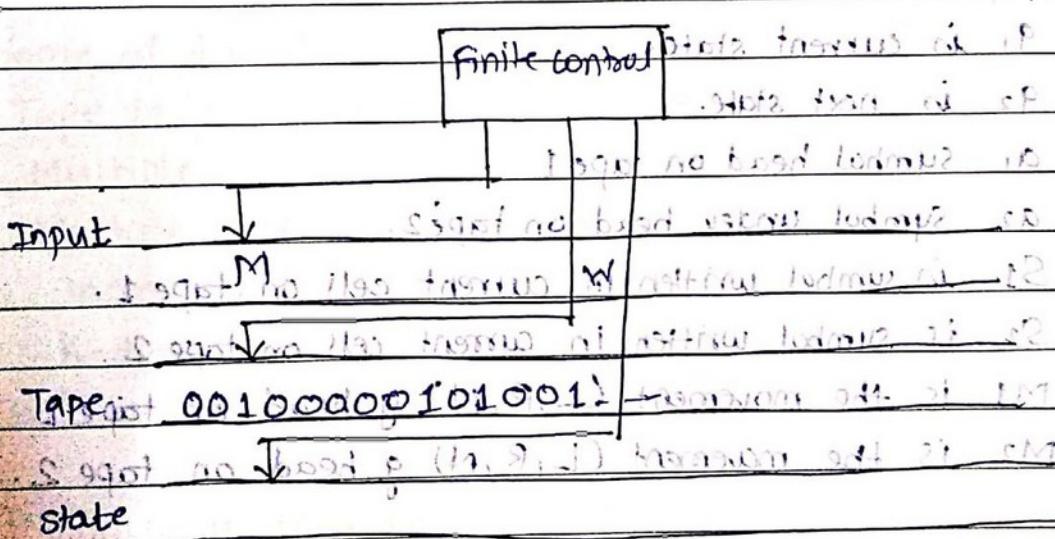

4) If head CFGS are given  $G_1$  &  $G_2$  then  $L(G_1) \cap L(G_2) = \emptyset$  is undecidable.

5) Recursively Enumerable lang. and the halting problem.

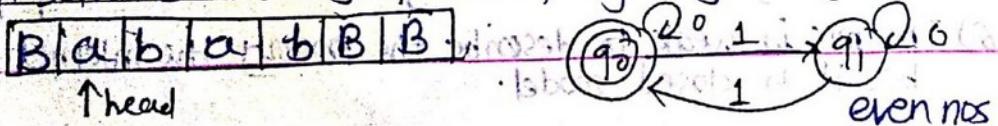

6) TM mtc is weak to describe the property like internet, evolution or robotics bcz it is closed model.

## \* Universal Turing Machine

- 1) The universal lang.  $L_u$  is the set of binary strings which can be modeled by turing m/c if it prints  $w$ .
- 2) The universal lang.  $L_u$  can be represented by pair  $(M, w)$  where  $M$  is a TM that accept this lang.  $w$  is binary string in  $(\{0, 1\})^*$  such that  $w$  belong to  $L(M)$ . Thus, we can say that any binary string belongs to universal language.
- 3) The universal lang.  $L_u$  can be represented by  $L_u = L(U)$  where  $U$  is universal Turing m/c.
- 4) In fact,  $U$  is binary string. This binary string represents various codes of many turing machine.
- 5) Thus, the universal turing m/c is a turing m/c which accepts many turing m/c ( $L_0, L_1, L_P$ ).

- \* Language acceptability by turing machine:
- TM accepts all lang even though there are recursively enumerable.
  - Recursive means repeating the same set g rule for any nsg times.
  - Enumerable means listing elements.
  - TM also accepts Computable function; such as Addition, multiplication, subtraction, division, power fun, square fun & logarithmic function.
  - we can solve some prob. for accepting lang using TM.

\* TM's Halting Problem  $\vdash$  (complement of SAT) is NP-Complete

" Halting Problem is unsolvable again for ci MT "

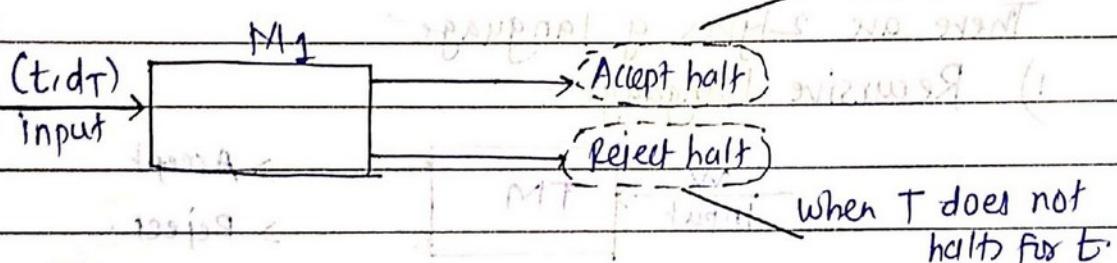

proof:  
by contradiction of this we consider contradiction

(let) there exist a TM  $M_1$  which decides whether or not  
any computation by a TM  $T$  will ever halt when a  
description of  $T$  and tape of  $T$  is given.

Then for every I/P  $(t, d_T)$  to  $M_1$  if  $T$  halts for I/P  $t$ .

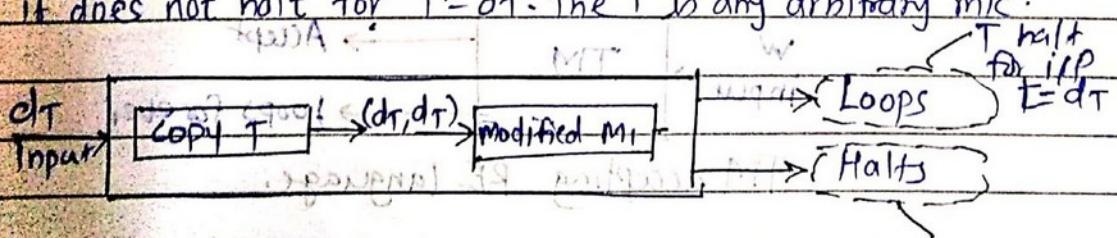

$M_1$  also halts which is called accept state

- similarly if  $T$  does not halt for I/P  $t$  then the  $M_1$  will  
halt which is called reject state

when we will consider another TM  $M_2$  which takes I/P  $d_T$ .

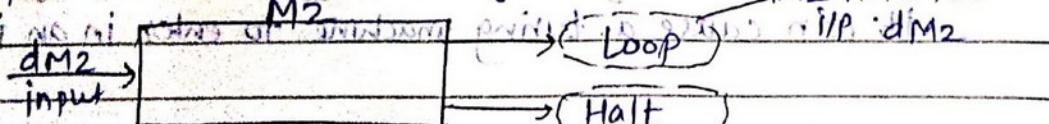

$M_2$  first copy  $d_T$  and duplicate it on its tape and then this  
duplicate tape info is given as I/P  $m_2$  to  $M_1$ . But  $M_1$  is modified not  
with the modification that whenever  $M_1$  finds a tape to  
reach an accept halt,  $M_2$  loops forever. Hence behaviour of  $M_2$   
is given: If loops if  $T$  halts for I/P  $t = d_T$  and  
halts if  $T$  does not halt for  $t = d_T$ . The  $T$  is any arbitrary m/c.

$M_1$  does not halt for  $t = d_T$ .

As  $M_1$  itself is a TM, we will take  $M_2 = T$ , that means:

we will replace  $T$  by  $M_2$  from above given m/c. with  $M_2$  halts for  
loop if  $t = d_T$  and  $M_2$  halts for  $t = d_T$  if  $M_2$  loops.

This is contradiction, that means  $M_1$  which can tell  
whether any other m/c TM will halt on particular I/P.  
does not exist. Hence halting problem is solvable.

$M_2$  does not  
halt for I/P  $d_M_2$ .

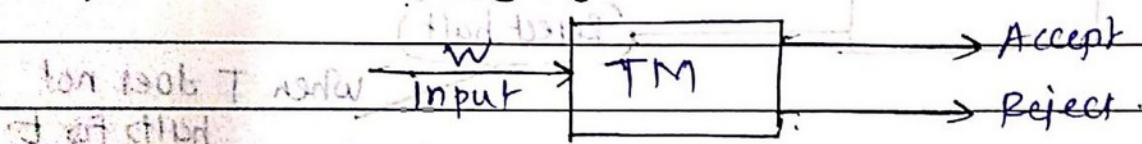

## \* TM and Type 0 Grammars

- TM can accept Type 0 grammar.
- The type 0 grammar is said to be unrestricted grammar.  
e.g. all restricted lang. are almost all natural lang.
  - The class of lang. accepted by type 0 grammar are called recursively enumerable language.
  - A string  $\alpha \rightarrow \beta$  can be in form  $(A \rightarrow B) \cup C$  where  $A$  and  $B$  are strings (terminal and non-terminal).

$B$  is string of terminal & non-terminal.

There are 2 types of language:-

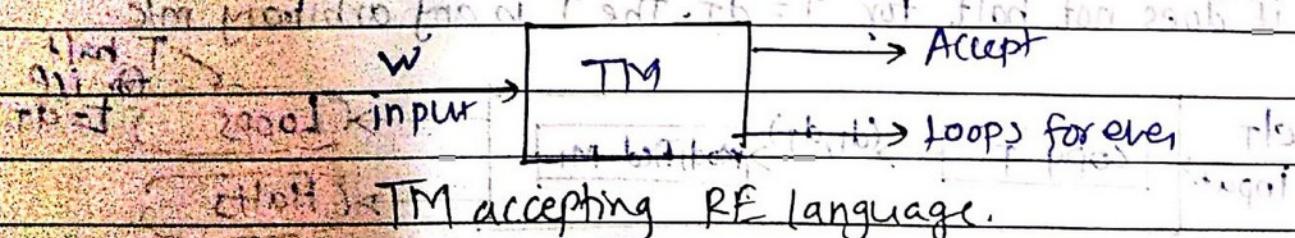

### 1) Recursive Language:-

TM Accepting Recursive Language

A lang. is said to be recursive if there exists a TM that accepts every string of lang. and rejects every string which is rejected if it's not belonging to that lang.

### 2) Recursively Enumerable Language:-

TM accepting RE language.

A lang. is said to be recursive if there exist TM that accepts every string belonging to that language. And if the string does not belong to that language then it can cause a turing machine to enter in an infinite loop.
