Q1. What is EJB? What are benefits of EJB.

Ans. • EJB stands for Enterprise JavaBean, which is a server-side component architecture within the Java EE platform designed for developing distributed, transactional, secure, and portable enterprise applications; its key benefit is that it allows developers to focus on business logic by offloading system-level services like transaction management, security, and persistence to the EJB container, simplifying complex application development.

→ Key benefits of EJBs:

1. Simplified development:

- Developers can concentrate on business logic without managing low-level details like database access, threading, and transaction handling, as the EJB container takes care of these tasks.

2. Transaction management:

- EJB provides declarative transaction management, allowing developers to define transaction boundaries with annotations or XML configurations, ensuring data integrity through automatic rollbacks in case of errors.

3. Scalability:

- EJB containers can manage bean instances efficiently, allowing applications to scale horizontally by creating new bean instances as needed.

4. Security:

- EJBs can leverage the security features provided.

Q2.

What are the types of Enterprise Bean?

Ans.

There are three types of EJB:

i) Session Bean:

- Session bean contains business logic that can be invoked by local, remote or webservice client.

• There are two types of session beans:

i) Stateful Session bean:

• Stateful session bean performs business task with the help of a state.

• Stateful session bean can be used to access various method calls by storing the information in an instance variable.

ii) Stateless Session bean:

• Stateless session bean implement business logic without having a persistent storage mechanism, such as a state or database and can use shared data.

2. Message Driven Bean:

• Like session bean, it contains the business logic but it is invoked by passing message.

3. Entity Bean:

• It summarizes the state that can be remained in the database.

• It is deprecated.

• Now, it is replaced with JPA (Java Persistent API).

• There are two types of entity bean:

i) Bean Managed Persistence:

ii) Container Managed Persistence

Q3. What is session bean?

Ans.: A ~~session~~ session bean in Java Enterprise Edition (JEE) is a server-side component that encapsulates business logic and is used to execute specific tasks for a client application, essentially acting as a middle layer to handle complex business operations on behalf of the client without exposing the underlying complexities of the server; it is considered a key part of the EJB (Enterprise JavaBeans) architecture.

→ Key points about session beans:

① Purpose:

- They are designed to handle client requests, perform business logic operations like calculations, database updates, or complex workflows, and return the results back to the client.

→ Types of session beans:

1. Stateless session beans:-

- Does not contain conversational state between client invocations, meaning each request is treated independently.

2. Stateful session bean:

- Maintains conversational state across multiple client requests within a single session, allowing for tracking within a single session, allowing for tracking of ongoing interactions.

→ Benefits:-

1. Abstraction

2. Transaction management

Q4. List the ACID properties of a transaction.

- Ans. • ACID is an acronym that refers to the set of 4 key properties that define a transaction: Atomicty, Consistency, Isolation and Durability.
- If a database operation has these ACID properties, it can be called an ACID transaction, and data storage systems that apply these operations are called transactional systems.
  - ACID transactions guarantee that each read, write, or modification of a table has the following properties.

→ Atomicty:

- each statement in a transaction (to read, write, update or delete data) is treated as a single unit.
- Either the entire statement is executed, or none of it is executed.

→ Consistency:

- ensures that transactions only make changes to tables in predefined, predictable ways.
- Transactional ~~consistency~~ consistency ensures that corruption or errors on your data do not create unintended consequences.

→ Isolation:

- When multiple users are reading and writing from the same table all at once, isolation of their transactions ensures that the concurrent transactions don't interfere with or affect one another.

→ Durability:

- Ensures that changes to your data by successfully executed transactions will be saved.

what are the differences between stateful session bean and stateless session bean?

Ans.	Feature	Stateful Session Bean	Stateless Session Bean
1.	Client Interaction	maintain state across multiple method calls for a specific client.	Does not maintain state; each method call is independent.
2.	State management	Stores conversational state related to a specific client session.	No state is stored; any instance can serve any client request.
3.	Instance sharing	Each client gets a dedicated instance.	Instances are shared among multiple clients to improve performance.
4.	Lifecycle	Longer lifecycle, tied short-lived; created to the client session and destroyed per request or managed by a pool.	
5.	Performance	Consumes more memory due to client-specific data.	More scalable and efficient due to instance reuse.
6.	Persistence	Can be passivated (serialized to disk) when inactive to save memory.	Not passivated; always active when needed.

Q6.

How to create responsive web page using Bootstrap?

Ans.

To make a website responsive using Bootstrap, you can use its grid system, responsive utility classes, and mobile-first approach.

→ Steps:

1. Set up your project
2. Include Bootstrap in your project
3. Create a responsive navigation bar
4. Implement a responsive grid system
5. Use responsive images
6. Customize your styles
7. Test responsiveness

→ Tops:

- Adjust each breakpoint for responsive design.
- Verify and adjust each breakpoint view from mobile, tablet, or various desktop browsers.
- Decrease font size for smaller screens
- Use responsive utility classes to show or hide elements based on screen size.
- To make Bootstrap tabs responsive, add a responsive class to the ul that is used to create the tabs.
- To make Google Maps responsive, add class .w-100 to the iframe element.
- With the open-source feature, developers can further enhance the responsiveness using online community support.
- The framework supplies a dev-based architecture, and developers need not write the code from scratch.
- The framework proposes pre-defined CSS classes to construct a responsive web page.
